

# Multi-site State Coordination Service (MUSIC)

ONAP Policy Meeting 6/6/2018  
Presented by Bharath Balasubramanian

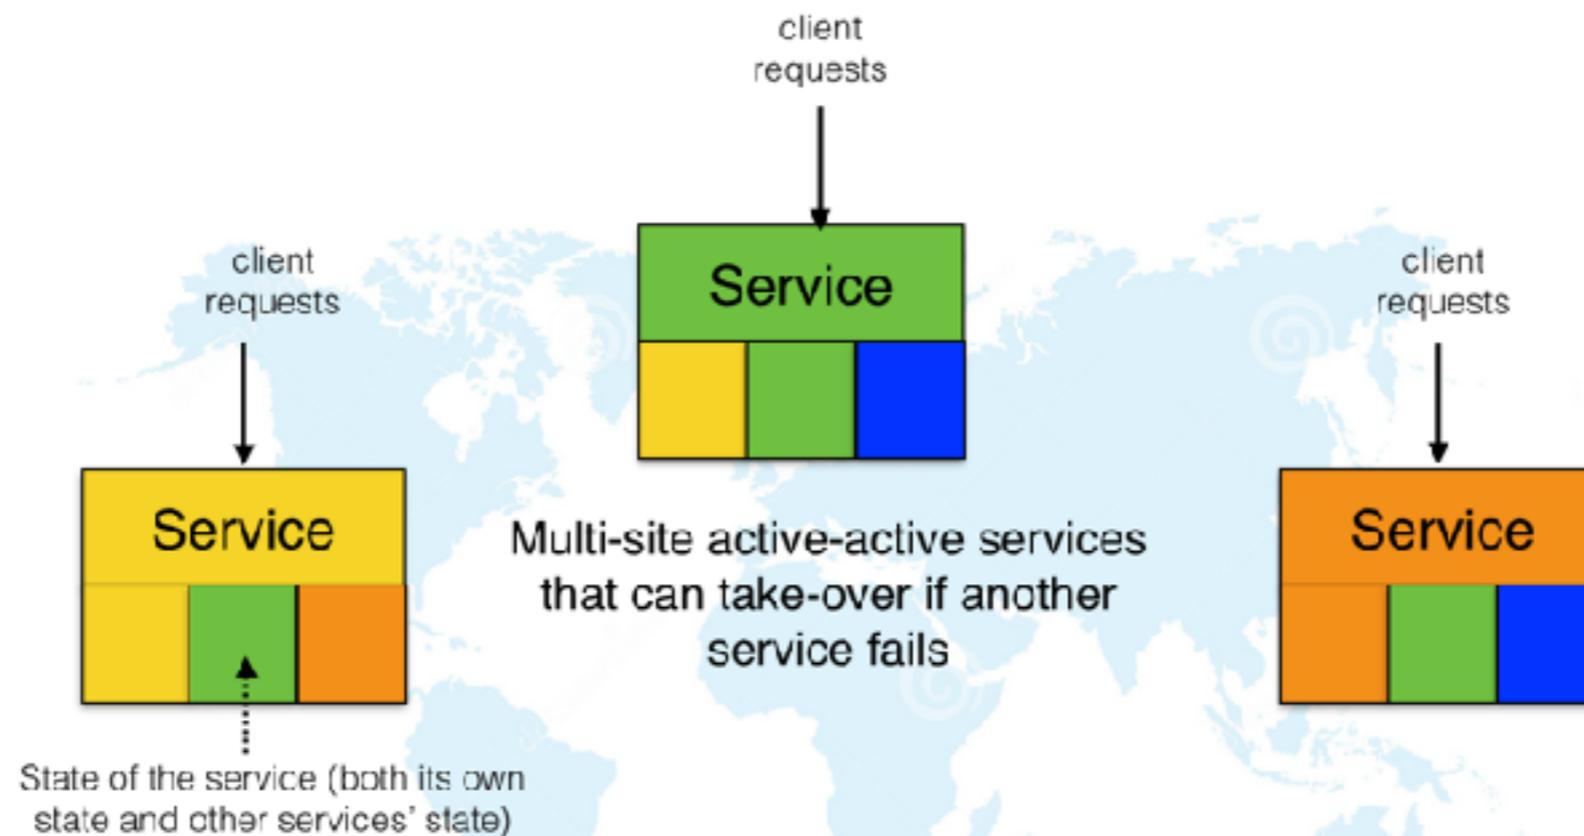

## Goal

A common state-coordination/management platform (**MUSIC**) to build VNFs with **5 9s of availability** on **3 9s** (or lower) **software and infrastructure** in a cost-effective manner.

# MUSIC Team

Responsibility	AVP	People
ONAP	NA	Bharath Balasubramanian (PTL, ATT), Viswanath Kumar Skand Priya (Verizon), Abbas Fazal (ATT), Thomas Nelson Junior (ATT), Greg Waines (Windriver), Brendan Tschaen (ATT)
Overall leadership and vision, D2 and ONAP evangelization	Oliver Spatscheck	Bharath Balasubramanian, Kaustubh Joshi
Design, architecture and prototypes	Oliver Spatscheck	Bharath Balasubramanian, Pamela Zave, Richard Schlichting, Shankar
Core development team	Gerald Karam	Abbas Fazal, Brendan Tschaen, Garima Mullick, Thomas Nelson, Chinnamma Charalel, Vaibhav Isanaka, Vikram Potturi, Inam Soomro, Srupane Kondreddy,
Integrating into ECOMP common software platform	Gerald Karam	Heather Robinett, Michael Howe
Benchmarking and testing	Catherine Lefevre	Chetan Doshi, Leonardo Bellini, Andrea Chiappa
Customers on board	Abbas Fazal and Gerald Karam (HAS-ATT/ONAP, Portal-ATT/ONAP, Valet (ATT), Sharon Chisholm, Jim Mount and Richard Trabedski (Amdocs POC for SDN-C-ATT)	

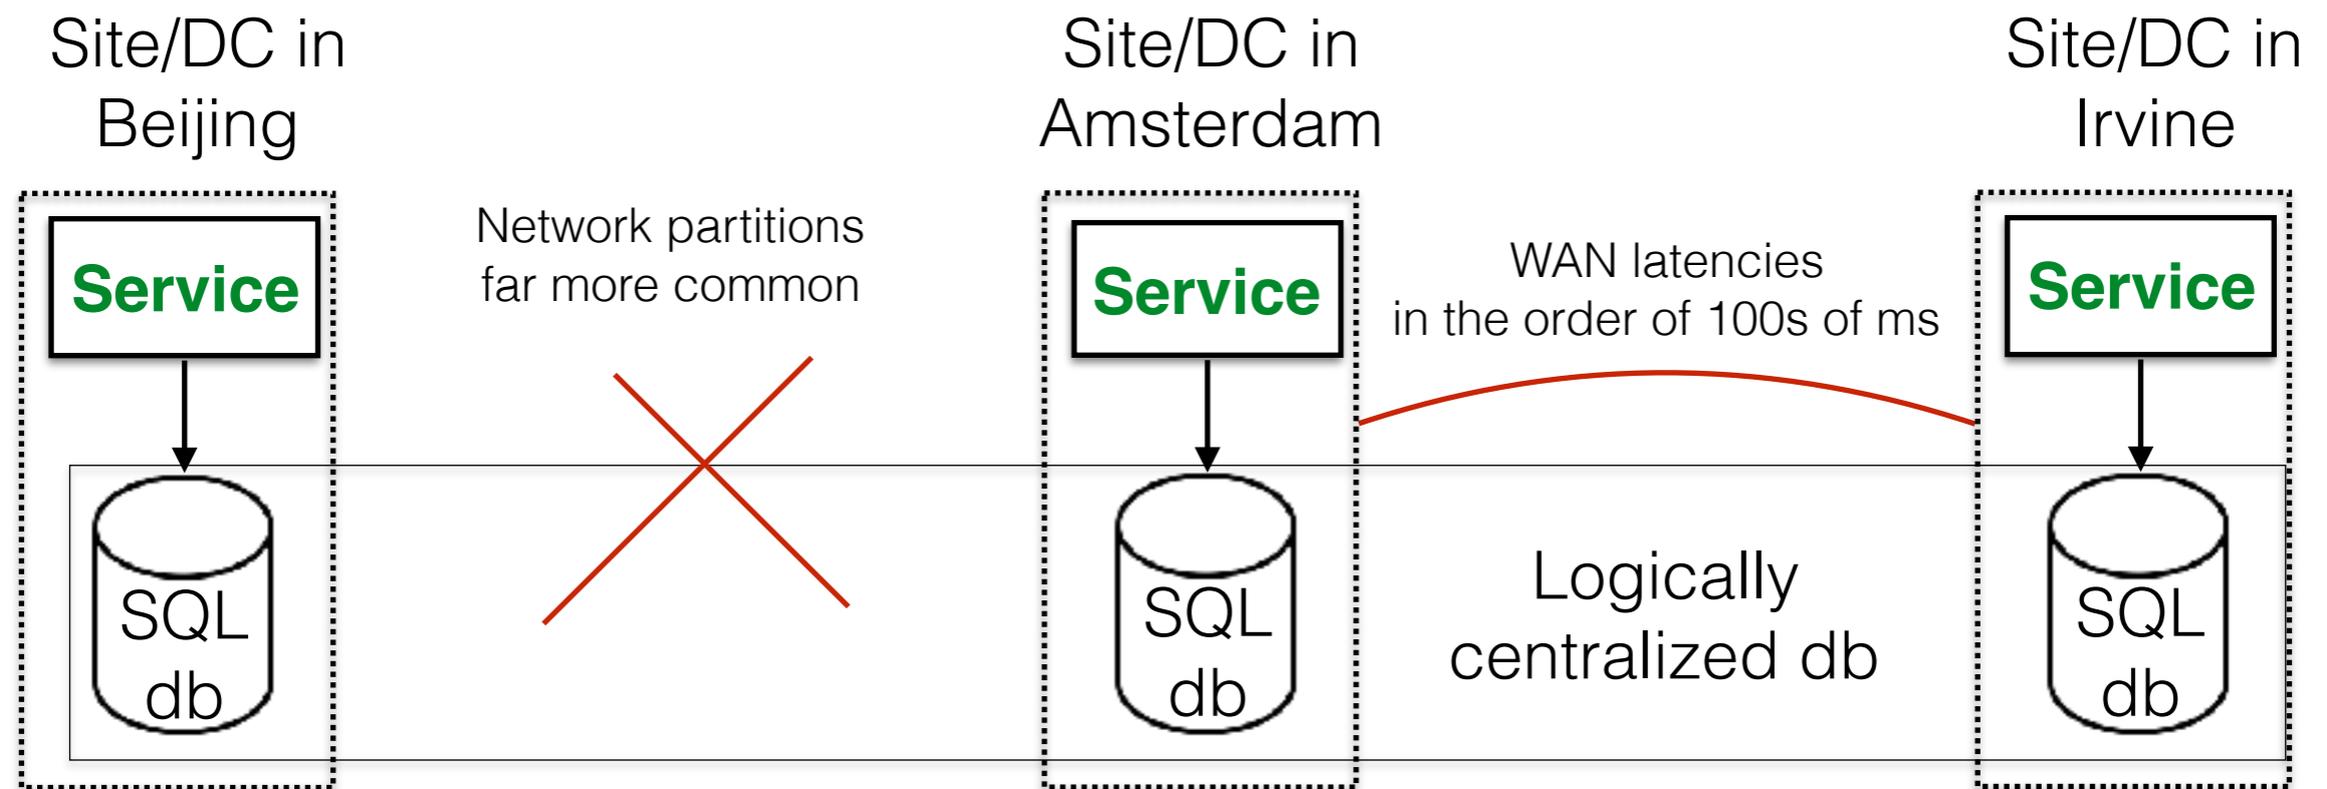

To achieve 5 9s availability network services (ONAP, VNFs, Edge/IoT services) need to support **multi-site**, **active-active** services with **efficient failover**.

# Need of the hour

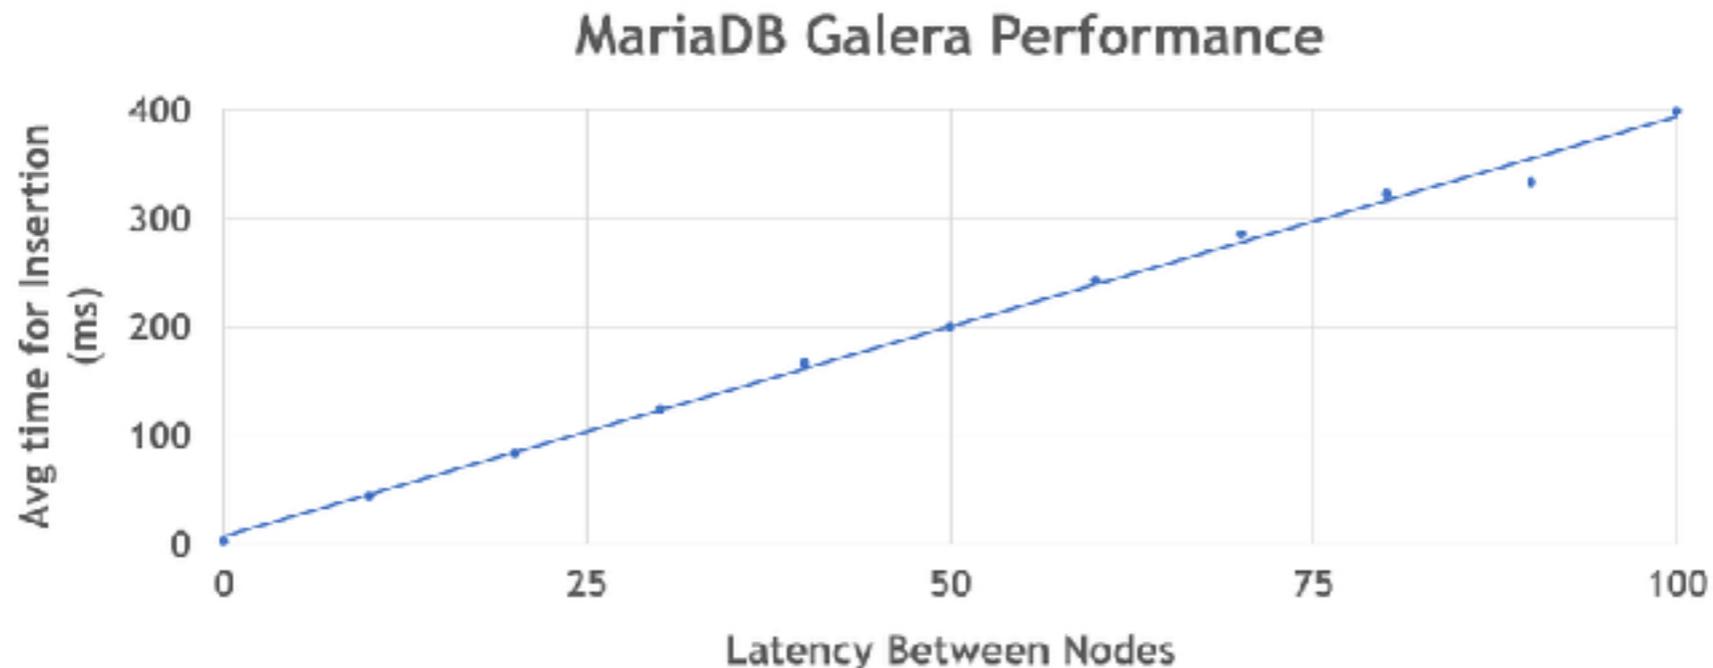

- Manage state of services across **thousands of geo-distributed sites.**
- Provide resiliency/coordination protocols to partition state across replicas and ensure **correct and efficient failover of state** during site-failures and site-partitions.

# Current Practice: May not scale.

Rooted in the philosophy “the single-site solution should more or less work across geo-distributed sites”. E.g. attempts to use MariaDB clustering as is across sites — **may not scale and/or allow partitioned operation!**

E.g: A preliminary study of MariaDB scalability across the world.

Simple 3 node cluster with latency using netem — nearly **half a second average insertion time** with 100 ms inter-node latency (typical of a US-East, US-West, Europe deployment of ONAP). Will be worse when we consider Irvine, Amsterdam, Beijing with > 200 ms latency.

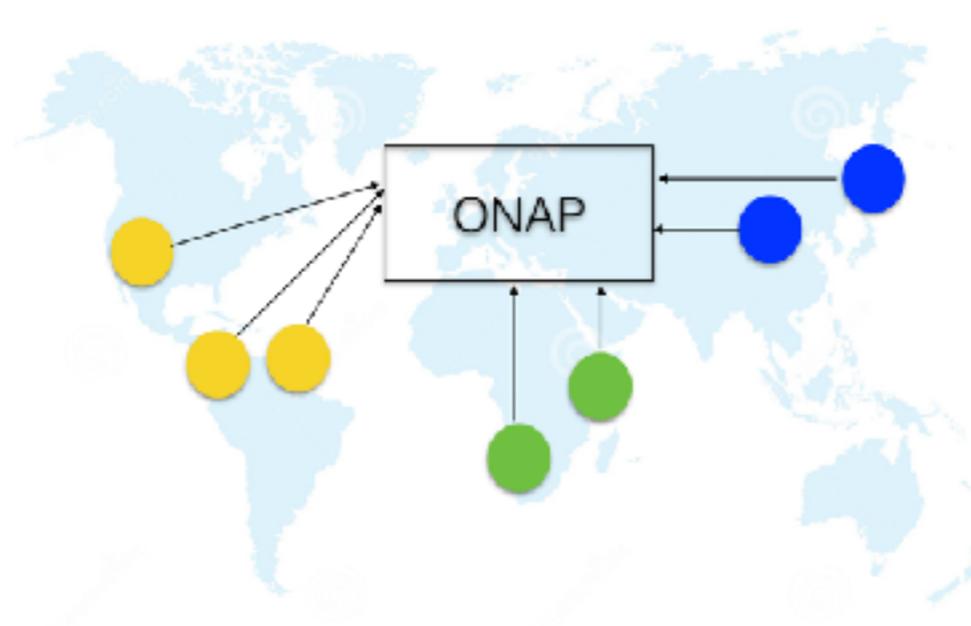

# Current Practice: Often wasteful and erroneous.

Each team building its own solution — **wasteful** and can often be **erroneous** due to complex distributed protocols, *replete with corner cases*. E.g.

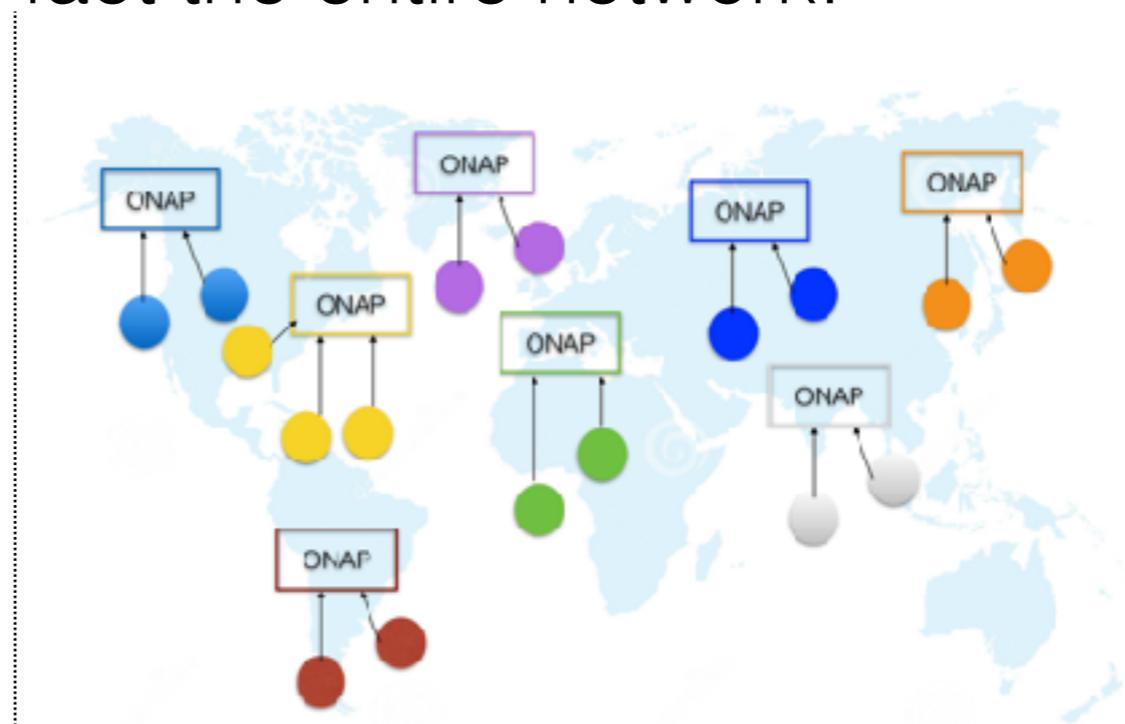

- How do you access state in a mutually exclusive manner when required despite failures/split brain issues?
- Does the new active have the latest information on failover?

# Current Practice: Does not address future needs.

Most current designs barely address active-active needs, and mostly ignore *federation* that is crucial for IoT/Edge. E.g. ONAP for Edge/5G and in fact the entire network!

Monolithic design of ONAP to control VNFs will not scale to the edge.

Federated design of ONAP to control VNFs is much more practical.

# Our solution: MUSIC

- A **common** state-management platform for ONAP components/micro-services specifically tailored for **multi-site geo-distributed replication and federation**.
- Provide rich resiliency/coordination recipes on top of MUSIC that ONAP components can **simply configure and use** — each team need not re-invent solutions.

# Base solution

MUSIC maintains replicated state in an **eventually-consistent data-store** (Cassandra) wherein the access to the keys can be protected using a **strongly consistent locking service** (Zookeeper/Consul/etcd).

# Why is it unique?

Despite site failures or network partitions, MUSIC guarantees that the **lock-holder to a key always reads and writes to the latest value of the key** (formally called entry-consistency\*) - no other tool today achieves this.

Formally verified MUSIC protocols using model checking.

\* Under review at the Principles of Distributed Computing Conference (PODC 2018)

# Why is it useful?

Through the MUSIC abstractions and entry-consistency property, ONAP components/services can achieve **fine-grained flexible consistency** on their replicated state across sites — acquire lock only when you need strong consistency.

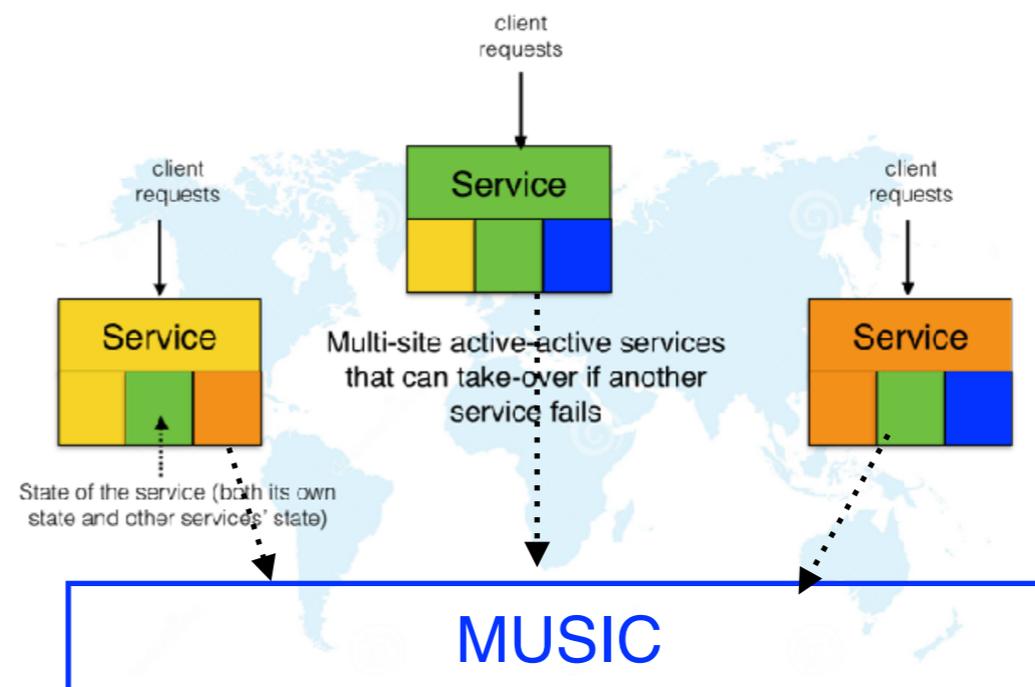

Provides a natural starting point for **federation** — the lock holder for a bunch of keys **owns** the state corresponding to those keys.

# Recipes

- **mdbc**: A plugin for components to migrate seamlessly from SQL usage to MUSIC
- **prom**: Policy driven ownership management of state to partition and failover state in a consistent manner
- **musicCAS**: Distributed compare and set across keys to perform atomic updates
- **musicQ**: A queue API across sites in which key management is carefully done to ensure efficient sorting

# MUSIC Vision of federation

- **MUSIC** ensures through **prom** that each service replica is the “owner” for a particular set of state corresponding to certain requests and assigns a few backups for this state (completely policy driven) on other sites
- The owner can now update state locally either directly to **MUSIC** or through **mdbc** for SQL-based components doing only quorum writes to other sites (**strong consistency without per operation locking!**)
- On site failure **prom** will transfer state ownership to another service on a different site and ensure the **new owner has latest state**.

Service = Any ONAP component/micro service/VNF

# MUSIC Implementation

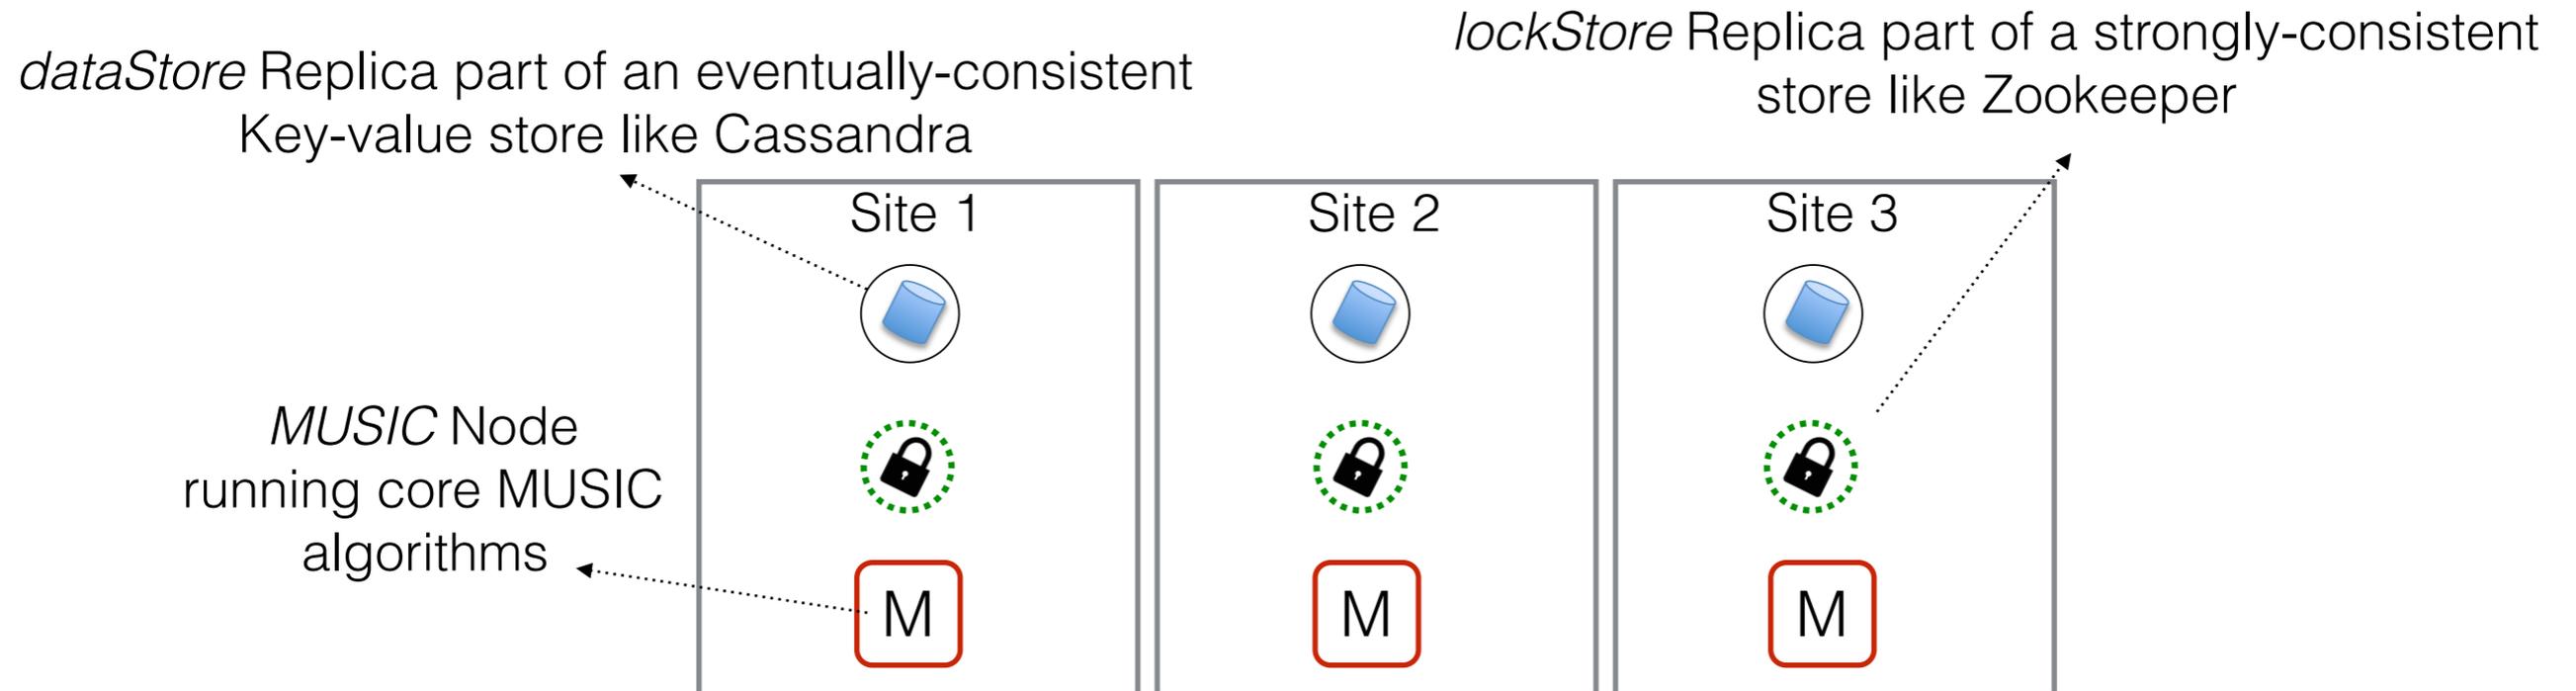

Thin shim layer (<10,000 lines) over two  
production tested open source tools —  
Apache Zookeeper and Cassandra provides  
you with 5 9s of availability!

# MUSIC Status

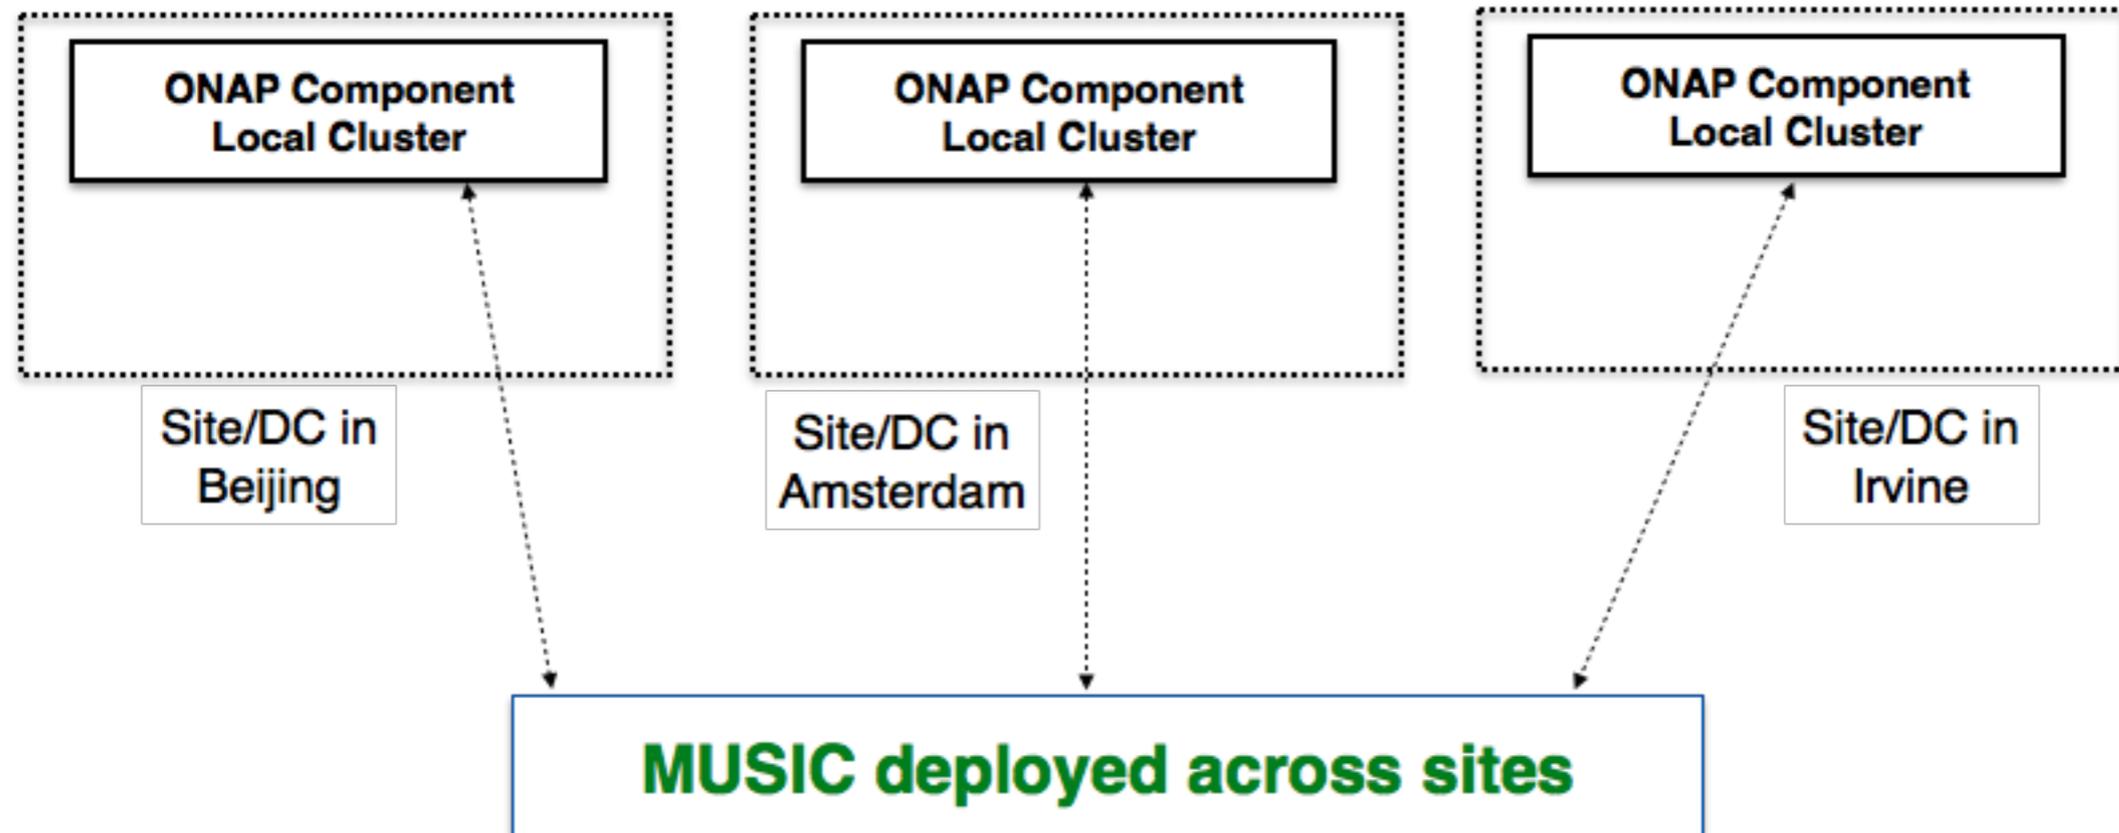

Use-Case	Status
ECOMP	<ul style="list-style-type: none"><li>• MUSIC in <b>production</b> 17/10 as the state management service of the ECOMP Homing Service (HAS) for SD-WAN.</li><li>• Currently integrating with Portal for 18/06</li><li>• SDN-C POC with Amdocs for 18/06</li><li>• Working actively with TechDev partners to make this the resiliency platform for all ECOMP services (18/19/xx)</li></ul>
ONAP	<ul style="list-style-type: none"><li>• Official ONAP Project recommended by architecture subcommittee for multisite state management</li><li>• R2 Beijing Release commitment from ONAP HAS and ONAP Portal</li></ul>
VNFs	Socialized the tool with Roman Pacewicz's team to solicit VNF
IoT/Edge Computing	Working with University partners to design and implement massively geo-distributed state-management architectures for IoT/Edge use-cases.

11- }
```

POST `http://{{node2}}:8080/MUSIC/rest/keyspaces/TestKS/tables/employees`

Authorization Headers (1) Body Pre-request Script Tests

form-data x-www-form-urlencoded raw binary JSON (application/json)

```
1- {
2-   "fields": {
3-     "emp_id": "uuid",
4-     "emp_name": "text",
5-     "emp_salary": "varint",
6-     "address": "Map<text,text>",
7-     "PRIMARY KEY": "(emp_name)"
8-   },
9-   "properties": {
10-    "comment": "Financial info of employees",
11-    "compression": { "sstable_compression": "DeflateCompressor", "chunk_length_kb": 64 },
12-    "compaction": { "class": "SizeTieredCompactionStrategy", "min_threshold": 6 }
13-  },
14-   "consistencyInfo": {
15-     "type": "eventual"
16-   }
17- }
```

The basic REST API provides a REST+JSON wrapper around the standard Cassandra API. While this is useful in itself, there is more...

# Locking API

The screenshot displays four REST client entries:

- Create lock to a key in Cassandra**: POST `http://localhost:8080/MUSIC/rest/locks/create/testks.employees.bharath`
- Acquire lock to a key in Cassandra**: GET `http://localhost:8080/MUSIC/rest/locks/acquire/$testks.employees.bharath$x-94608776321630281-0000000000`
- Update column (eventual)**: PUT `http://(node0):8080/MUSIC/rest/keyspaces/TestKS/tables/employees/rows?emp_name=joe`. The body is a JSON object: 

```
{  "values": {    "address": {      "street": "thomas street",      "city": "nyc"    }  },  "consistencyInfo": {    "type": "eventual"  }}
```
- Update column (atomic)**: PUT `http://(node0):8080/MUSIC/rest/keyspaces/TestKS/tables/employees/rows?emp_name=bharath`. The body is a JSON object: 

```
{  "values": {    "corp.salary": 4000  },  "consistencyInfo": {    "type": "atomic"  }}
```

The novel locking API allows the client to create locks on keys (that guarantees mutually exclusive access). Further, the client can choose between **eventual operations (no locks)** and **atomic operations on keys (uses locks in a critical section)**!

mdbc: multi-site  
database cache

# mysql Basic

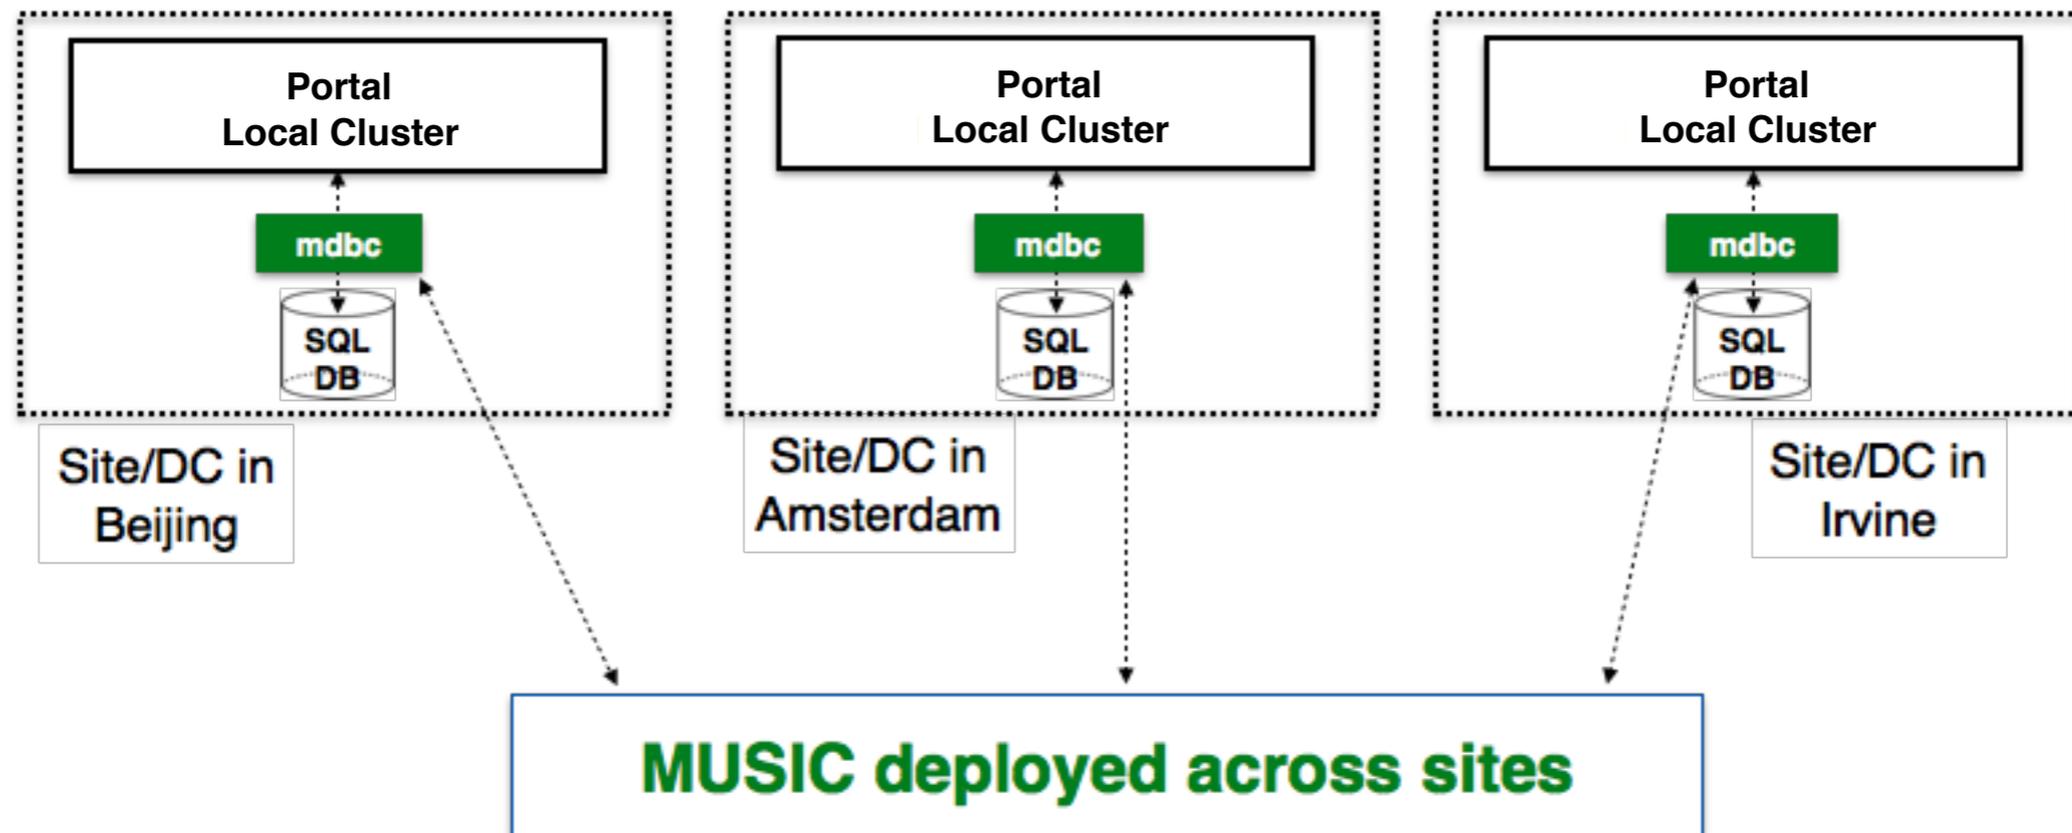

A plug-in for SQL-based components to seamlessly use MUSIC with **no change to SQL code.**

Ensures transactional guarantees within a site with **per-key choice of sync or async replication** across sites.

# mdbc Design

- mdbc = local sql db + multi-site MUSIC deployment
- Service replicated across multiple sites; writes to and reads from the local mdbc sql database
- mdbc captures local sql writes and propagates it to MUSIC and captures local reads and serves it from MUSIC

# mdbc Usage

SQL DB = within site  
MariaDB Galleria cluster for Portal

# mdbc config

## Before:

```
//Register JDBC driver
Class.forName("com.mysql.jdbc.Driver");
//Open a connection
Connection conn =
DriverManager.getConnection(DB_URL,
connectionProps);
```

## After:

```
//Register MDBC driver
Class.forName("org.onap.mdbc.ProxyDriver");
//Open a connection
Connection conn =
DriverManager.getConnection(MDBC_DB_URL,
connectionProps);
```

mdbc properties file:

```
music_address=1.2.3.4
```

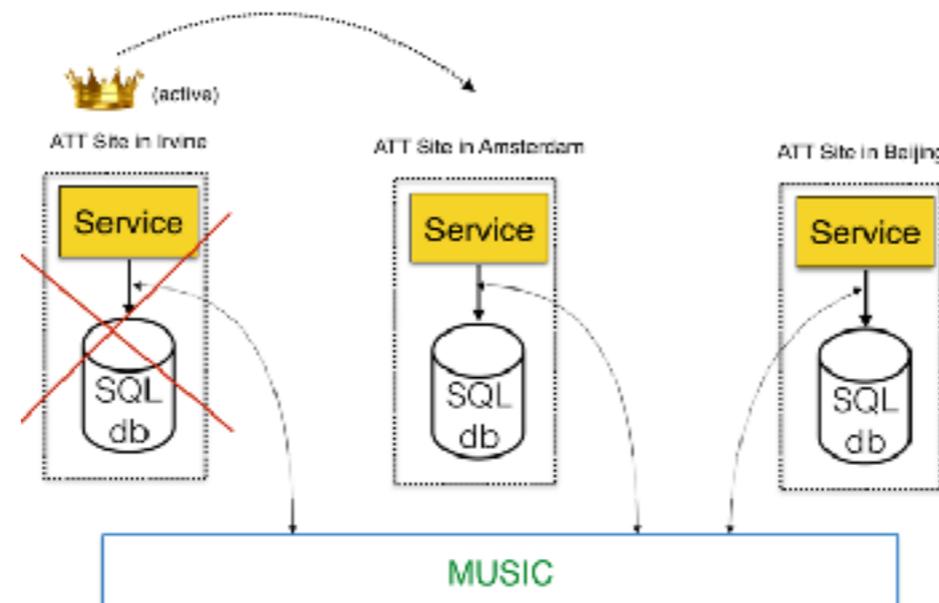

```
music_sync_tables= task, job, process
```

```
music_r_factor=3
```

prom: policy-driven state  
ownership management

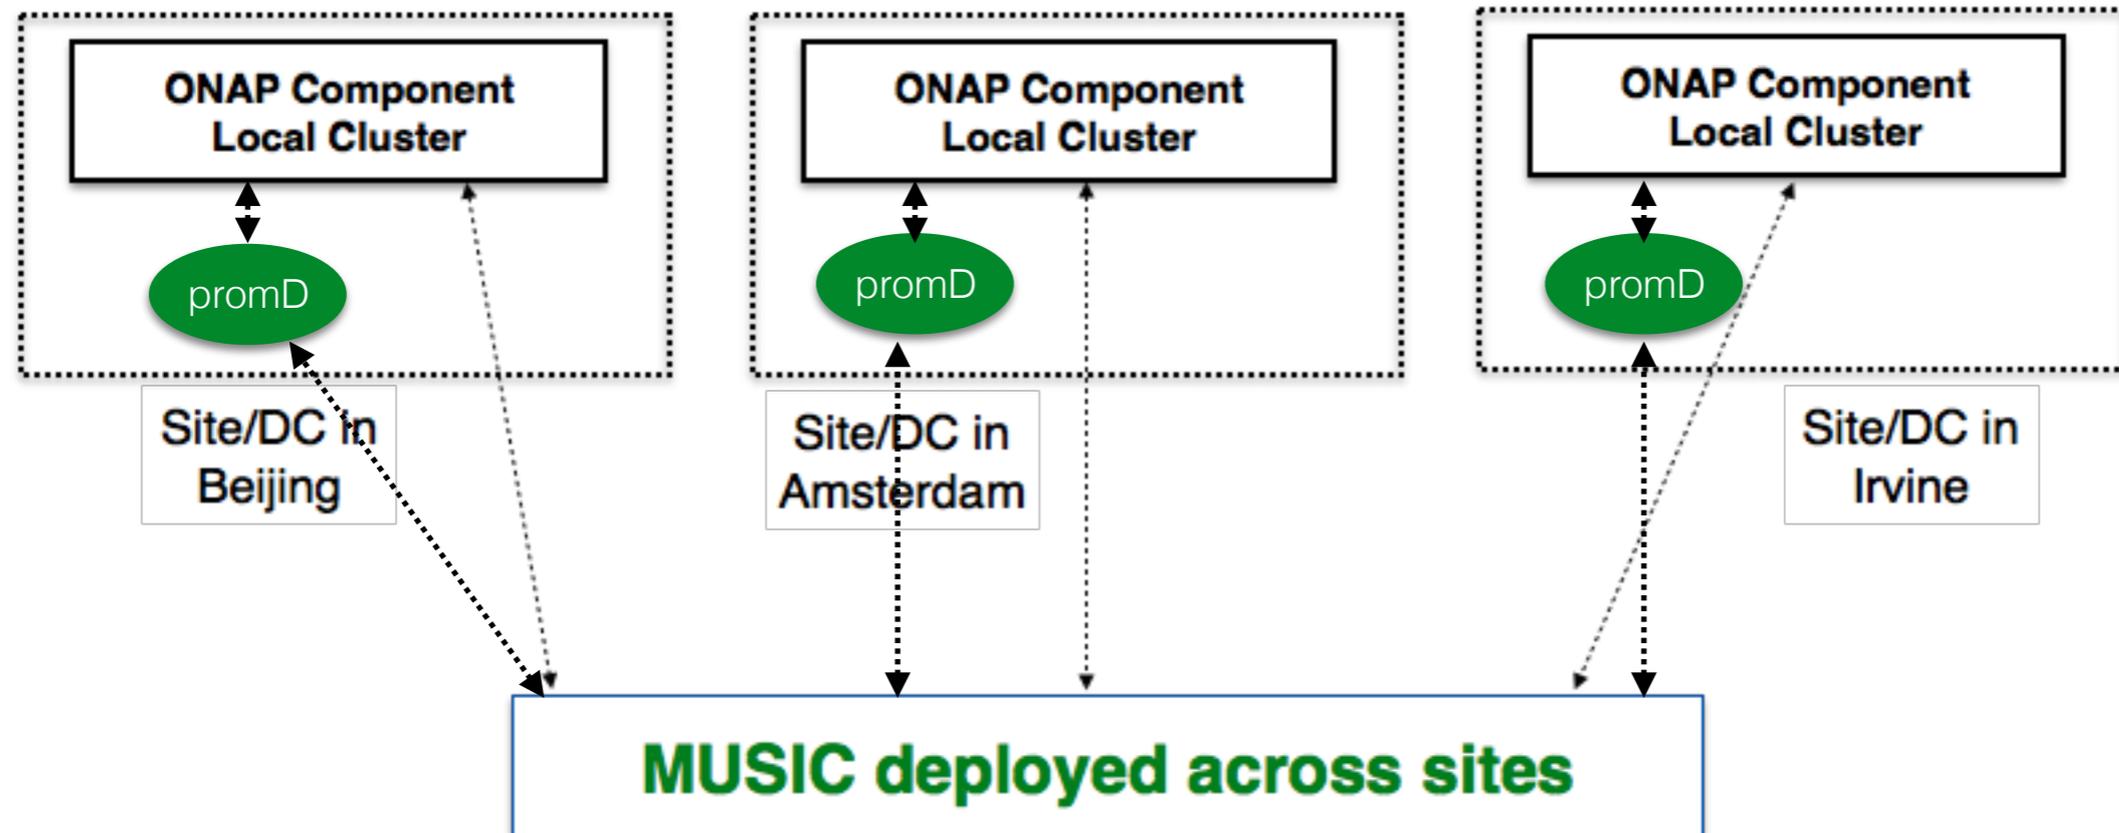

# prom: policy-driven ownership management

Detecting failure of a service and transferring ownership of state to a standby on another site involves **complex distributed system challenges, replete with corner cases.**

PROM provides recipes on top of MUSIC that services **can simply configure (policy-driven)** to achieve different resiliency patterns: active-standby, active-active with failover etc.

# prom Usage

# prom config

```
