Generating AAI API Docs

A&AI REST API Documentation

Generate the swagger like v8 to v11 spec via (thanks LiZi)

```
cd aai/aai-common/aai-core/
mvn -PgenerateXsd -DskipTests
mvn -PgenerateXsd install -DskipTests
mvn -PgenerateYaml install -DskipTests
mvn -PgenerateHtml install -DskipTests
cat ../aai-schema/src/main/resources/aai_swagger_html/aai_swagger_v8.html
cat ../aai-schema/src/main/resources/aai_swagger_html/aai_swagger_v11.html
```

The Active and Available Inventory (AAI or A&AI) has its own REST API.

The AAI REST API provides access to the AAI active inventory graph. The API is largely configured from models and configuration files. Each vertex in the graph has an API that can be called separately or, if part of a tree structure, as a nested element with one or more generations (parent, grandparent, and so on).

The edges of the graph are provisioned using a relationship list construct. For PUT methods, a relationship contains the vertex type or category (related-to) and a list of relationship data which captures the key pieces of data required to uniquely identify the resource. On a GET method, the above information and a URL are returned. The URL can be used to GET all the details of that object. The URL returned is suitable for retrying failed commands but should not be expected to be cacheable for very long periods (e.g., the version of the URL may get deprecated when the release changes).

API Definition

The API structure is composed of:

- The HTTP command, which indicates the operation to perform
- The HTTP URI, which defines what object this operation is related to
- The HTTP version, which MUST be 1.1

Available HTTP commands are:

- PUT: used to create or update an object
- DELETE: used to delete an object or a set of objects
- GET : used to query an object or set of objects
- PATCH : used to update specific fields owned by the client doing the update

The HTTP URI is built according to this pattern:

`https://{serverRoot}/{namespace}/{resource}`

- {serverRoot} refers to the server base url: hostname+port+base path+version. Port and base path are OPTIONAL but AAI will use port 8443 and base path aai. The first release version will be v8.
- {namespace} refers to the API namespace. Supported namespaces are cloud-infrastructure, business, service-design-and-creation, and network
- {resource} refers to how the object is identified according to the namespace specifications.

Example

GET `https://{host-url}:8443/aai /v8/cloud-infrastructure/cloud-regions/cloud-region/{cloud-owner}/{cloud-region-id}`

Postman example

The screenshot shows the Open ECOMP API client interface. The sidebar on the left lists various API endpoints under the 'A&AI' category. The main panel displays a GET request to the endpoint `https://{{aai_ip}}:8443/aai/v8/service-design-and-creation/services`. The request configuration includes headers such as `Accept: application/json`, `Content-Type: application/json`, `X-FromAppld: AAI`, `X-TransactionId: get_aai_subscr`, and `Authorization: Basic QUJOkFBSQ==`. The response panel shows a JSON array of service objects, with the status `200 OK` and a response time of `154 ms`.

Logs

```
aaiadmin@vm1-aai:/opt/app/aai/logs$ pwd
/opt/app/aai/logs
aaiadmin@vm1-aai:/opt/app/aai/logs$ cat ajsc-jetty/localhost_access.log
